- What is “list” in R?

A list in R is a collection of data which can hold a variety of data types such as numbers, strings, vectors and another list. List can be called a vector containing other objects. It is ordered and changeable. We can create a list in R by using the `list()` function.

- How to create a list containing strings, numbers, vectors and logical values in R?

We can create a list containing strings, numbers, vectors and logical values in R by using the below code in RStudio:

```
my_list <- list("Statistics",'R', 100, c(1,2,3), TRUE)
```

Here, ‘my_list’ is the name of list and it contains following elements:

1. strings ("Statistics",'R')
2. number (100)
3. vector (c(1,2,3))
4. logical value (TRUE)

- How to name the list elements in R?

We can name the elements of a list by using the `names()` function in R.

```
my_list <- list("Statistics",'R', 100, c(1,2,3), TRUE)
```

```
names(my_list) <- c("string_element1","string_element2",  
"numeric_element", "vector_element", "logical_element")
```

The `names()` function is used to assign names to each element of the list 'my_list'. The `c()` function is used to create a vector. The resulting list `my_list` will have the names "string_element1", "string_element2", "numeric_element", "vector_element", and "logical_element" assigned to each element respectively.

- How to assess list elements in R?

We can access the elements of the list using their assigned names or index. For example, to access the elements of 'my_list' we use the following code in R.

Using assigned names:

```
my_list$string_element1  
my_list$string_element2  
my_list$numeric_element  
my_list$vector_element  
my_list$logical_element
```

Using List Index:

```
my_list[1]
```

```
my_list[2]
```

```
my_list[3]
```

```
my_list[4]
```

```
my_list[5]
```

- How to manipulate list elements in R?

We can manipulate the elements of a list in various ways. We can add, delete, and update list elements. Here are some common operations we can perform on list elements:

1. Adding elements:

We can add new elements to a list in many ways like using list index, using the `c()` or `list()` function. For example:

Adding a new element using list index :

```
my_list[6] <- "new_element"
```

Adding a new element using `c()` :

```
my_list <- c(my_list, "new_element1")
```

Adding a new element using `list()` :

```
my_list <- list(my_list, "new_element2")
```

This third approach of adding elements into the list will make the nested list.

2. Removing elements:

We can remove elements from a list using the `[-]` operator.

Removing the first element :

```
my_list <- my_list[-1]
```

Remove the last element using list index:

```
my_list[6] <- NULL
```

3. Updating list elements:

We can modify list elements by assigning new values to them using their index or name.

Modifying the first element using index

```
my_list[[1]] <- "Data Science"
```

Modifying the second element using name

```
my_list[["string_element2"]] <- "Python"
```

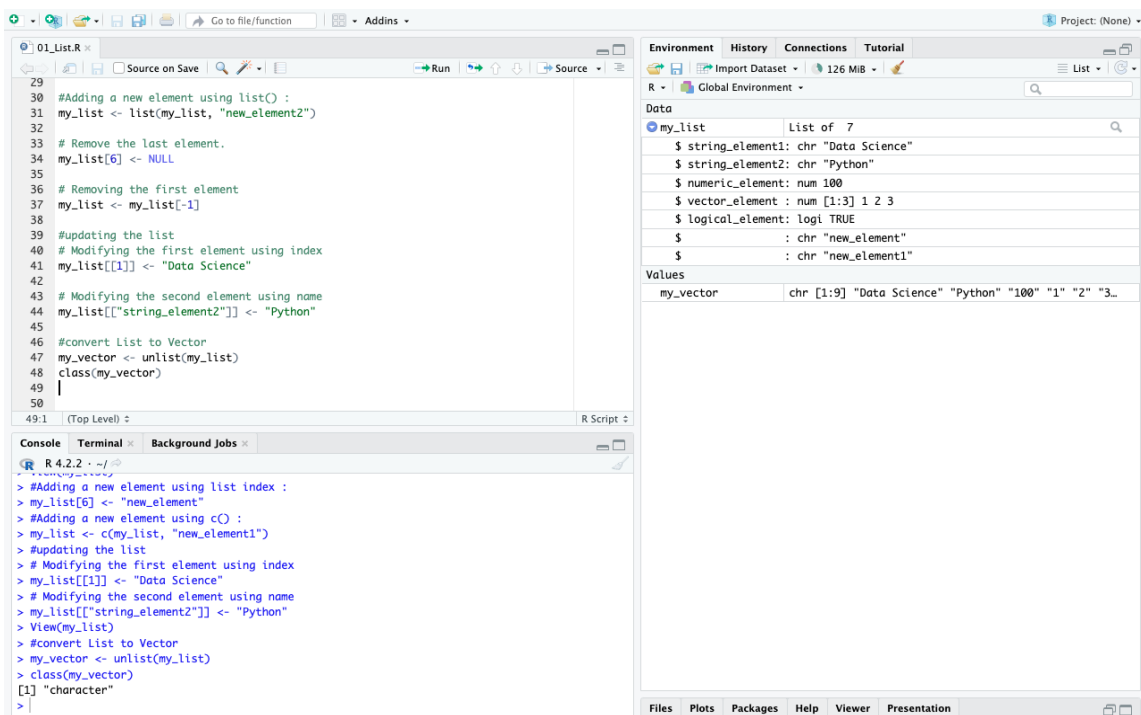

- How to convert lists to vectors in R?

We can convert a list to a vector in R using the `unlist()` function.

```
my_vector <- unlist(my_list)
```

By compelling all elements to a common type, `unlist()` function will attempt to simplify the resulting vector as much as possible. Because the list includes a mix of character, numeric, vector, and logical elements in this example, the resulting vector will be of type character, because character is the common type that can hold all of the elements in this case.

All above R codes are compiled from RStudio:

The screenshot shows the RStudio interface with the following components:

- Source Editor:** Contains R code for creating a list, modifying it, and converting it to a vector.
- Environment:** Shows the objects in the global environment, including `my_list` (a list of 7 elements) and `my_vector` (a character vector).
- Console:** Displays the output of the R code, showing the structure of the list and the resulting character vector.

```
# Adding a new element using list() :
my_list <- list(my_list, "new_element2")

# Remove the last element.
my_list[6] <- NULL

# Removing the first element
my_list <- my_list[-1]

# updating the list
# Modifying the first element using index
my_list[[1]] <- "Data Science"

# Modifying the second element using name
my_list[["string_element2"]] <- "Python"

# convert List to Vector
my_vector <- unlist(my_list)
class(my_vector)
```

Environment:

Object	Class	Value
my_list	List of 7	\$ string_element1: chr "Data Science" \$ string_element2: chr "Python" \$ numeric_element: num 100 \$ vector_element: num [1:3] 1 2 3 \$ logical_element: logi TRUE \$: chr "new_element" \$: chr "new_element1"
my_vector	chr [1:9]	"Data Science" "Python" "100" "1" "2" "3..."

Console:

```
R 4.2.2 > # Adding a new element using list index :
R 4.2.2 > my_list[6] <- "new_element"
R 4.2.2 > # Adding a new element using c() :
R 4.2.2 > my_list <- c(my_list, "new_element1")
R 4.2.2 > # updating the list
R 4.2.2 > # Modifying the first element using index
R 4.2.2 > my_list[[1]] <- "Data Science"
R 4.2.2 > # Modifying the second element using name
R 4.2.2 > my_list[["string_element2"]] <- "Python"
R 4.2.2 > View(my_list)
R 4.2.2 > # convert List to Vector
R 4.2.2 > my_vector <- unlist(my_list)
R 4.2.2 > class(my_vector)
[1] "character"
R 4.2.2 >
```
